3.2.2.4 ENLARGE

Calling Sequence:

```
LD    A, TABLE_CODE
LD    DE, SOURCE
LD    HL, DESTINATION
LD    BC, COUNT
CALL  ENLARGE
```

Description:

ENLARGE takes each generator in a block of COUNT generators following SOURCE in the table indicated by TABLE_CODE and from it creates four generators as shown below in Figure 3-7.

| | |
|---------------------|---------------------|
| first generator | third generator |
| second generator | fourth generator |

Figure 3-7
ENLARGE Generators Layout

The enlarged object will appear to be a double-sized version of the original. The created generators are put back into a block of $4 * \text{COUNT}$ generators following DESTINATION in the same table.

Note that since the ordering of the expanded generators is the same as that for the four generators needed to produce a size 1 sprite, ENLARGE lends itself well to use with sprites as long as the programmer is willing to dedicate four times as many sprites to the expanded object as to the original.

If TABLE_CODE is 3 (indicating the pattern generator table) and the graphics mode is 2, ENLARGE makes four

1 copies of the color table entry for each source
2 generator and places them in the color table so that
3 they correspond to the four destination generators.
4 This should mean that the color scheme for the enlarged
5 object will be the same as that of the original. If the
6 mode is 1, the color table is untouched.

7
8 Parameters:

9
10 TABLE_CODE VRAM table code (Ref. Table 3-1)
11 to be operated upon.

12
13 SOURCE SOURCE is the two-byte index of
14 the first entry in the specified
15 table to be operated on.

16
17 For table operations on a sprite
18 generator or a pattern generator
19 in graphics mode 1, SOURCE should
20 be in the range $0 \leq \text{SOURCE} \leq$
21 255. For pattern generators in
22 mode 2, it should be in the range

18
19
20
21
22
23
24
25
26

1 0 <= SOURCE <= 767. In either
2 case, if a value of SOURCE is
3 supplied and is outside the
4 table's range but still a legal
5 VRAM address, the specified number
6 of "entries" will be read and
7 modified from the VRAM location
8 (table location) + 8 * SOURCE.
9 For the proper table entries and
10 table boundary, refer to Table
11 3-2.

12
13 Sprite size has no effect on the
14 range of SOURCE.

15
16
17 DESTINATION

18 DESTINATION indexes the place
19 where ENLARGE will start placing
20 generators back into VRAM after
21 modifying them.

22 The same restrictions apply to the
23 value of DESTINATION as to the
24
25
26

1 value of SOURCE. They are both
2 intended to be indices into the
3 same generator table.

4
5 COUNT

6 A two-byte count of the number of
7 entries to be processed
8 sequentially after SOURCE.

9 The most important factor limiting
10 the size of COUNT in the case of
11 the ENLARGE routine is that
12 ENLARGE actually produces four
13 generators for every generator
14 that it reads.

15
16 The legal value for count depends
17 on the size of the table being
18 operated on and the values of
19 SOURCE and DESTINATION. Both of
20 the following statements should be
21 true:

22
23
24
25
26

1
2
3 3.2.3 Sprite Reordering Software
4

5 Probably the most significant hardware limitation of the
6 VDP is the so-called "fifth sprite problem." This
7 problem arises when more than four sprites occur on a
8 single horizontal scan line. Because the chip only has
9 four registers for dealing with the lower order sprites,
10 the sprites with the higher sprite attribute indices
11 cannot be generated on that scan line and therefore
12 disappear.

13
14 One solution to this problem is to use a reordering
15 scheme on the offending sprites which involves swapping
16 the priorities of the sprite that is being blanked out
17 with that of one of the higher order sprites in the
18 group on successive video fields. The result is that
19 while the sprites that are being reordered tend to
20 flicker in the area of overlap, they are still quite
21 visible. The degree of flicker depends on many factors
22 including the color of the sprites in question and the
23 background color and complexity.
24
25
26

1 The OS supports this solution by allowing the
2 application to adjust the order of sprite attribute
3 entries with minimum effort.

4
5 Two tables are used in implementing the sprite
6 reordering feature. The first of these is simply a
7 local CRAM version of the VRAM sprite attribute table.
8 It must be allocated by the application program and made
9 accessible to the OS by placing a pointer to it at the
10 predetermined cartridge ROM location LOCAL_SPR_TBL.
11 This local sprite attribute table need only contain the
12 active sprite entries needed by the application and
13 therefore may be shorter than the 128 bytes required for
14 the VRAM version. The other table is called the sprite
15 order table. It is also allocated by the application
16 program through a pointer, SPRITE_ORDER, located in
17 cartridge ROM. The sprite order table should contain
18 one byte for each entry in the local sprite attribute
19 table, and the bytes should take on values in the range
20 $0 \leq b \leq 31$.

21
22 When the flag MUX_SPRITES is false (0), PUT_VRAM writes
23 sprite attribute entries directly to VRAM. However,
24
25
26

1 when this flag becomes true (1), they are written
2 instead to the local sprite attribute table. Then, a
3 routine called WR_SPR_NM_TBL will map the local sprite
4 attribute entries to VRAM according to the sprite order
5 table.

6
7 An example of the relationship between the three tables
8 may be illustrated as follows:
9

26

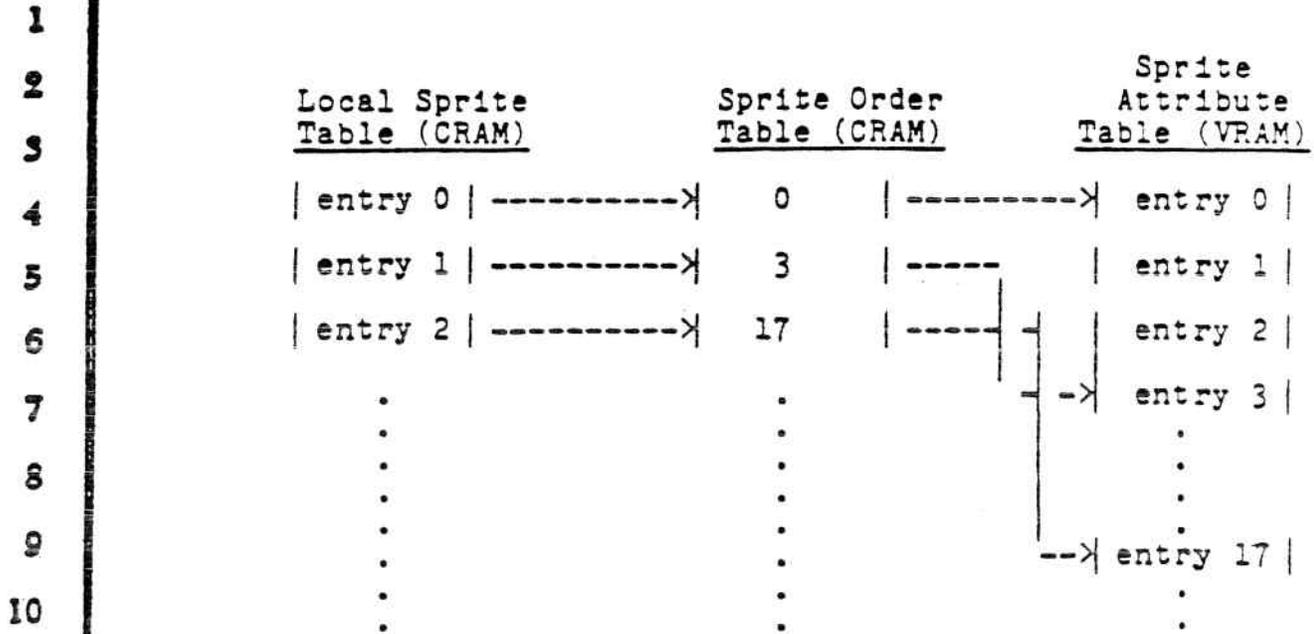

Figure 3-8

Sprite Reordering Table Mapping

The advantage of this method lies in the fact that it takes a lot less work to reorder the bytes in the sprite order table than it does to move around the entries in the VRAM or CRAM sprite attribute tables.

1
2
3 3.2.3.1 INIT_SPR_ORDER
4

5 Calling Sequence:

6
7 LD A, SPRITE_COUNT
8 CALL INIT_SPR_ORDER
9

10 Description:

11
12 INIT_SPR_ORDER looks at the pointer SPRITE_ORDER in low
13 cartridge ROM which should contain the address of a free
14 area SPRITE_COUNT bytes long in CRAM. It sets this area
15 up as a sprite order table by initializing it with
16 zero through SPRITE_COUNT - 1.
17

18 Parameters:

19
20 SPRITE_COUNT The length of the sprite order
21 table, which would be the same
22 as the intended number of entries
23 in the local sprite attribute
24 table.
25

21
22
23
24
25
26

This number must always be in the
range $1 \leq \text{SPRITE_COUNT} \leq 32$.

Side Effects:

- Destroys AF, BC, and HL.

1
2
3 3.2.3.2 WR_SPR_NM_TBL
4

5 Calling Sequence:

6
7 LD A, COUNT
8 CALL WR_SPR_NM_TBL
9

10 Description:

11
12 WR_SPR_NM_TBL writes COUNT entries from the local sprite
13 attribute table, which it accesses through the pointer
14 LOCAL_SPR_TBL in low cartridge ROM, to the VRAM sprite
15 attribute table. The transfer is mapped through the
16 sprite order table which it accesses through the pointer
17 SPRITE_ORDER in low cartridge ROM.
18

19 Parameters:

20
21 COUNT This is the number of sprite
22 attribute entries to be written to
23 VRAM.
24
25
26

1
2
3 3.3 Object Level

4
5 The object level software constitutes the top level of
6 the graphics generation software, which appears to the
7 user as a collection of screen objects with well-defined
8 shape, color scheme, and location at any given moment.
9 The software supports four distinct object types, each
10 of which has its own capabilities and limitations. Once
11 objects are defined, however, the rules for manipulating
12 them are fairly type-independent. In fact, only one
13 routine (PUTOBJ), is used to display objects of all
14 types.

15
16 Brief descriptions are given in the following sections
17 in regard to object types, object data structures and
18 two user-accessible routines (ACTIVATE, PUTOBJ). For
19 further information, refer to Appendix B.

20 3.3.1 Object Types

21
22 There are four different types of objects defined by the
23 OS. A brief description for each type is given below.
24
25
26

1 3.3.1.1 Semi-Mobile
2

3 Semi-mobile objects are rectangular arrays of pattern
4 blocks which are always aligned on pattern boundaries.
5 Their animation capability is limited. In most cases
6 they are used to set up background pattern graphics.
7

8 3.3.1.2 Mobile
9

10 The size of a mobile object is fixed in two-by-two
11 pattern blocks. They belong to the pattern plane but
12 can be moved from pixel to pixel in X,Y directions like
13 a sprite superimposed on the background. However, the
14 speed of mobile objects are too slow when compared to
15 the sprites.
16

17 3.3.1.3 Sprite
18

19 Sprite objects are composed of an individual sprite.

22
23
24
25
26

3.3.1.4 Complex

Complex objects are collections of other "component" objects which may be of any type including other complex objects.

3.3.2 Object Data Structure

Each of the above mentioned objects has its definition in cartridge ROM. This high-level definition links together several different data areas which specify all aspects of an object. The data structure is described in detail in Appendix B.

3.3.2.1 Graphics Data Area

This data area is located in cartridge ROM. Pattern and color generators for semi-mobile, mobile and sprite objects and frame data for all objects are located in the graphics data area. The data structure within each graphics area depends on the type of object with which it is associated. If, however, two or more objects of the same type are graphically identical, they may share

1 the same graphics area. This will reduce the amount of
2 graphics data that needs to be stored in cartridge ROM.

3
4 3.3.2.2 Status Area

5
6 Each object will have its own status area in CRAM. The
7 game program uses this area to manipulate the object.
8 It does this by altering the location within status
9 which determines which frame is to be displayed as well
10 as the locations which define the position of the object
11 on the display. The graphics routine, PUTOBJ, when
12 called, will access the object's status area and place
13 the object accordingly.

14
15 3.3.2.3 OLD_SCREEN

16
17 Mobile and semi-mobile objects appear in the pattern
18 plane. They are displayed by altering some of the names
19 in the pattern name table. The original names represent
20 a background which is "underneath" the object. When the
21 object moves or is removed from the pattern plane, the
22 original names must be restored to the name table.

1 Before placing a semi-mobile or mobile object on the
2 display, PUTOBJ will restore any previously saved names
3 and also save the names which constitute the background
4 underneath the new location of the object. Sprite and
5 complex objects do not need OLD_SCREEN areas.

6
7 3.3.3 ACTIVATE

8
9 Calling Sequence:

10
11 LD HL, OBJ_DEF
12 SCF
13 CALL ACTIVATE

14
15 or

16
17 LD HL, OBJ_DEF
18 OR A
19 CALL ACTIVATE

20
21
22
23
24
25
26

1 Description:
2

3 The primary purpose of this routine is to move the pat-
4 tern and color generators from the graphics data area
5 into the pattern and color generator tables in VRAM.
6 Each object must be "activated" before it can be
7 displayed. ACTIVATE also initializes the first byte in
8 an object's OLD_SCREEN data area with the value 80H.
9 PUTOBJ tests this location before restoring the
10 background names to the name table. If the value 80H is
11 found, it is an indication that there are no background
12 names to restore.
13

14 Parameters:
15

16 OBJ_DEF High level definition of an
17 object. See Appendix B for
18 further details.
19
20 SCF Carry flag should be set if user
21 wishes to load the generators spe-
22 cified for this object.
23
24
25
26

1 OR A Carry flag should be reset if user
2 knows that the generators are
3 already in VRAM.
4

5 3.3.4 PUTOBJ
6

7 Calling Sequence:
8

9 LD IX, OBJ_DEF
10 LD B, BKGND_SELECT
11 CALL PUTOBJ
12

13 Description:
14

15 PUTOBJ is called when an object's frame or its
16 location on the display is to be changed. The routine
17 tests the type of object and then branches to one of
18 several subroutines designed to handle that particular
19 object type. These routines are not accessible to the
20 user. Their functions are as follows:
21
22
23
24
25
26

1. PUT_SEMI

Semi-mobile objects are placed on the display by writing the generator names specified by one of the object's frames into the pattern name table in VRAM. The pattern and color generators which are needed to create the frame must already be in their respective generator tables.

2. PUT_MOBILE

Mobile objects are displayed by producing a new set of pattern and color generators which depict the frame to be displayed on the background. These new generators are then moved to the locations in the VRAM pattern and color generator tables which are reserved for the object; the names of the new generators are then written into the pattern name table.

3. PUT_SPRITE0

PUT_SPRITE0 handles the display of size 0 sprite objects.

1 4. PUT_SPRITE1

2
3 PUT_SPRITE1 handles the display of size 1 sprite
4 objects.

5
6 5. PUT_COMPLEX

7 PUT_COMPLEX calls PUTOBJ for each of its
8 component objects.

9
10 Parameters:

11
12 OBJ_DEF High level definition of an
13 object. See Appendix B for
14 further details.

15
16 BCKGND_SELECT Used with mobile objects or
17 complex objects with a mobile-type
18 component. Can be ignored other-
19 wise. For methods of selecting
20 background colors in a mobile
21 object. Refer to Appendix B for
22 additional information.
